conductors). Tomsk, Izd-vo Tomskogo univ., 1964, 205-218

TOPIC TAGS: gallium arsenide, gold alloy, silver alloy, semiconductor research,
semiconducting material

ABSTRACT: The authors study the process of formation, structure and some properties of fused gallium arsenide contacts with gold and silver. The melting points, coefficients of thermal expansion and microhardness of the various alloys formed at the semiconductor-metal contact were measured. Alloys of gallium arsenide with silver have a melting point of 750-760°C. The melting point of the gallium arsenide-gold alloy produced in a vacuum is 350-360°C, while that produced in an argon Card 1/2

I 00709-66

3

atmosphere is 575°C. This indicates that the composition of alloys of gallium arsenide with gold depends on the conditions under which the alloys are formed. Alloys with gold prepared in argon showed the least change in the coefficient of linear expansion. Alloys produced in vacuum have coefficients of linear expansion close to those of the pure metals. All the alloys differ considerably in their expansion coefficients from gallium arsenide, which may be the reason for the considerable thermal stresses which arise in alloyed contacts of gallium arsenide with gold and silver. Microhardness for all alloys is considerably lower than that of gallium arsenide. X-ray structural analysis shows that the gallium arsenide-silver contacts are composed of eutectic silver and polycrystalline GaAs. The interaction between gallium arsenide and gold in vacuum produces a chemical compound. The gallium arsenide-gold contact produced in argon gas is composed of eutectic gold and gallium arsenide. Contacts of gallium arsenide with gold and silver may be used as ohmic contacts. Orig. art. has: 7 figures, 3 tables.

TITLE: Preparation of Plane Allicyed Contacts with Germanium (Polucheniye ploskikh splavnykh kontaktov s germaniyem)

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, fizika, 1958,
Nr 5, pp 60-64 (USSR)

ABSTRACT. Properties of semiconducting devices depend on the geometry of the p-n junction. The properties of the junction itself are determined by the degree of wetting of germanium by the metal used and the mutual solubility of the two. The present paper deals with the causes of formation and ways of elimination of undissolved patches in junctions of germanium with indium. Such patches depend on the method of preparation of indium and germanium, on the crystal orientation of the germanium surface and on the heat treatment applied in alloying. Good wetting depends not only on the purity of the germanium surface but also on the purity of indium. The authors etched indium before alloying and they found that a picric acid etchant was most effective. After etching with picric acid the indium surface becomes mirror-clean and the structure of indium can be clearly seen (Fig. 1a - indium before etching, Fig. 1b - after etching). M. P. Yakuben' found that the structure which can be seen after etching represented mono-

Card 1/3

SOV/139-58-5-12/35

Preparation of Plane Alloyed Contacts with Germanium

crystalline grains of indium. The authors studied the process of wetting of germanium by etched and unetched indium, using germanium surfaces of various orientations, such as (111), (110), (100). Various methods of alloying were also tried. Alloying was carried out with the apparatus described in Ref. 4, which makes it possible to photograph the indium drop in various stages of alloying. From these photographs the angle of wetting could be determined. After producing alloyed contact, the indium was etched away with hydrochloric acid and the contact surface was then studied under the microscope. The authors make the following conclusions from the results obtained. 1) If unetched indium discs are used, then there will be always some patches of the contact surfaces which are not wetted by indium (Fig. 2). Better results are obtained when either etched discs or unetched spheres of indium are used. The best results are achieved by the use of etched spheroidal lumps of indium; in this case no unwetted areas were found (Fig. 3). Similar results were obtained for an alloy of indium with 0.5% of gallium. Additional gallium reduces

Card 2/3

SC074100-5-12/35

Preparation of Plane Alloyed Contacts with Germanium.

the wetting ability of indium (Fig.4). 2) The effect of crystal orientation of the germanium surface appears in the anisotropy of wetting; the smallest angle of wetting is obtained when the (111) surface is used. This is shown in Fig.5, which gives the temperature dependence of the angle of wetting of germanium by indium for the (111) (curves 1 and 3) and (110) (curve 2) planes. To achieve the best p-n junctions, the authors suggest using spheroidally-shaped etched indium and (111) germanium surfaces. The temperature rise in the process of alloying should be about 250-300°C per hour. The junction diameter was of the order of 2 mm when 10-12 mg of indium were used. The authors thank V. A. Presnov who directed this work. There are 5 figures and 7 references, 4 of which are Soviet and 3 English.

PURPOSE: This collection of articles is intended for the general reader interested in the mechanization and automation of machine-tool production

COVERAGE: The efforts of industrial workers of the Penza district to fulfill ahead of time the objectives set forth in the Seven Year Plan are discussed in these 11 articles. The need for complete automation in the production of machine tools and instruments is strongly emphasized. No personalities are mentioned. There are no references.

THE POSSIBILITY OF OCCURRENCE OF μ^0 -MESON
PENETRATING RADIATION DURING COLLISIONS BE-
TWEEN HIGH ENERGY PROTONS AND NUCLEI. A. N.
Novikov, R. M. Pontecorvo (Pontekorvo), and G. I. [113]
Sivanyov (Selinianov). Translation of a pre-print from
I.P.N. P. Acad. of Sci., U.S.S.R. by M. B. Karella, '71.
"The abnormal scattering" of μ mesons cannot be ex-
plained by interaction between the nucleon field and the
field of (μ, μ^0) pair. It is also concluded that the
"structural" theory of mesons as proposed by Weizel is
not correct and that the contribution of (μ, μ^0) pair inter-
action to the nuclear forces is insignificant. (auth)

Title : Possibility of the formation of Λ^0 particles by protons with
energies up to 700 Mev

Periodical : Zhur. eksp. i teor. fiz., 29 September 1955, 265-273

Abstract : The authors attempt to observe the formation of Λ^0 particles
during collision of protons with energies of 670 Mev with carbon
nuclei. In principle the experiments permitted them to record
 Λ^0 particles decaying according to the following scheme: $\Lambda^0 \rightarrow$
 $n + \pi^0$. They detected gamma rays from the decay of π^0 mesons by
means of a telescope consisting of scintillational and Cherenkov
counters. They find that the cross section of formation of Λ^0
particles has a value approximately equal or less than 10^{-31}
cm²/nucleon. They draw conclusions concerning the mechanism gov-
erning the formation of Λ particles. The authors thank V. V
Krivitskiy and A. I. Mukhin for assistance in setting up the col-
limator. Ten references, mainly western and to Otchet IIYaP AN

Periodical : Zhur. eksp. i teor. fiz., 29, No 6(12), Dec 1955, 889-892

Title : A communication based upon the results of a work carried out in 1954 and earlier described in Otchet Instituta Yadernykh Problem AN SSSR (Reports of the Institute of Nuclear Problems, Acad. Sci. USSR). The authors propose here that the virtual process $(N) \rightarrow (N) + (\mu, \mu)$ (N : nucleon) takes place, as also indicated by others (e.g. R. E. Marshak, Mesons physics, 1952). They describe experimental arrangement, consisting of target, collimator, deflecting magnet, telescope of scintillation counters serving as monitor, telescope of proportional counters serving as detector of penetrating radiation, convertor, counter filled with BF_3 , etc. They call attention to related work of B. Feld et alii (Phys. Rev., 96, 1386, 1954), noted just as they completed the work described here. They remark on the agreement of results. Eight references, all Western but one (cited above).

TITLE: An eight litre hydrogen-deuterium bubble chamber in a magnetic field

PERIODICAL: Prirody i tehnika atomizmata, no.5, 1960, 51-59

TEXT: A detailed description of the apparatus is given. Essentially it consists of two nested cylinders, the inner space being the working volume and the outer space for a magnetic field control. The inner cylinder is of glass to improve heat transfer and the outer cylinder, together with most of the casing, is constructed from LMK-97 (LMK-97T) stainless steel. Observation ports at the ends of the inner cylinder consist of discs of LK-5 (LK-5) glass 40 mm thick and with an aperture of 280 mm. Detailed drawings are given of the expansion apparatus and the associated two stage double acting electromagnetic valve. The normal gas pressure for operating the expansion apparatus is 7 atm and the degree of expansion can be altered by changing the

An eight litre hydrogen balloon.

The quantity of liquid hydrogen required to cool the chamber and balloon, the elastic bellows and the detector assembly to the required temperature is about 10 litres. The filling of the chamber and the balloon is done by a spark gap system fed from a standard 12 volt battery. The pressure of liquid in the liquid hydrogen tank is measured by a standard manometer and the pressure is read at the working voltage of 1200 volts. The liquid oxygen tank is filled with standard MC-4 (100%) liquid oxygen. The liquid oxygen tank has a capacity of 10 litres. Liquid nitrogen must be added to the oxygen tank above the cooling. Checks were observed to be made after the chamber was filled to fill the working volume. The time was less than 6 hours. The time to fill the working volume was about 30 litres. with liquid hydrogen in about 10 minutes and oxygen about 20 litres. During operation 0.3 to 0.5 millilitres of liquid oxygen was used. During operation a typical track showing the elastic consumed. A photograph of a typical track showing the elastic consumed is shown. The chamber has been used satisfactorily for a month during which time 50000 stereo photographs were obtained. The expansion apparatus has performed about 70000 cycles without changing the balloon. There are 15 figures. The dead time of the chamber has not exceeded 3 sec. Figures are 15 figures.

AUTHORS: Balandin, M.P., Grebinnik, V.G. and Selivanov, G.I.
TITLE: Synchronization of the operation of a bubble chamber
with a synchrocyclotron
PERIODICAL: Pribory i tekhnika eksperimenta, no. 5, 1962,
60 - 64

TEXT: The usual method of designing the synchronization circuit for a bubble chamber relies on a number of series-connected binary circuits and in this system the spread of the fronts of the triggering pulses can amount to 3% of the total duration of the delay pulse. This, in practice, produces an additional time error of about 0.9 μ s, which completely obscures the growth period of the bubbles to visible dimensions. The system described does not suffer from the above fault due to the production of a coincidence between the internal signal and the synchronization pulse in the final stage. The photographic-exposure time is matched with the instant of passage of the beam to within 10^{-4} sec. The system is provided with a "type-of-operation" switch which permits the actuating of the system by

Card 1/3

S/120/62/000/005/010/056

E192/E382

Synchronization of the operation..

the start pulses obtained from the photo pick-up of the accelerator (external actuation) or by trigger pulses produced by an internal generator. In either case, the system can operate continuously or only once. The internal drive is useful during the testing and adjustment of the system and permits testing the chamber independently of the accelerator. In order to provide definite intervals for the growth of the bubbles after passage of the beam through the accelerator the instant of producing the illumination pulse is made variable. Also, relative time-spacing of the other control pulses is unaltered. This is achieved by providing a delay circuit at the input of the system for the synchronization pulses. The synchronization pulses from the accelerator appear at intervals of 8 - 12 μ s, whereas the operating cycle of the chamber is 2 - 5 sec. Stable operation of the system as a whole is therefore achieved by blocking it for the duration of the operating cycle as soon as a start pulses is received. The blocking pulse is produced by a special forming circuit which blocks the chamber for a duration of 0.5 - 30 sec. A single start pulse triggers therefore two independent channels:

Card 2/3

S/120/62/000/005/010/036
Synchronization of the operation.. E192/E382

a system for forming pulses for controlling operation of the electromagnetic valve and a unit for producing the illumination pulse. Both channels comprise delay circuits permitting the shifting of the inception of expansion, the starting of contraction and the instant of triggering of the spark tube. It is possible to select the optimum position of the illumination pulse by shifting the instant of expansion. There are 6 figures.

Measurement of the total cross ...

determination of the cross section of reaction (3) only cases where the energy of the emitted gamma quantum was higher than 100 Mev were considered. In order to obtain a representation of the contribution of the different isotopic states in the cross sections of the reactions (1) and (2), the latter are written down in the form

$$\sigma_1 = \frac{1}{9} \left[\frac{1}{5} |A_{\frac{1}{2}}^{(1)}|^2 - 2 \sqrt{\frac{2}{5}} \operatorname{Re}(A_{\frac{1}{2}}^{(1)} A_{\frac{3}{2}}^{(1)}) + 2 |A_{\frac{3}{2}}^{(1)}|^2 \right] + \frac{1}{9} |A_{\frac{1}{2}}^{(2)}|^2 - 2 \operatorname{Re}(A_{\frac{1}{2}}^{(2)} A_{\frac{3}{2}}^{(2)}) + |A_{\frac{3}{2}}^{(2)}|^2,$$

$$\sigma_2 = \frac{1}{10} |A_{\frac{3}{2}}^{(1)}|^2 + \frac{1}{9} \left[\frac{1}{2} |A_{\frac{1}{2}}^{(1)}|^2 + 2 \operatorname{Re}(A_{\frac{1}{2}}^{(1)} A_{\frac{3}{2}}^{(1)}) + 2 |A_{\frac{3}{2}}^{(1)}|^2 \right],$$

where A_K^i denotes the invariant isotopic amplitudes (superscript refers to total isotopic spin of entire system, subscript denotes total isotopic spin of the system of two pions). The cross sections of the reactions (1) and (2) permit with some assumptions to infer the following about the magnitudes and phases of the isotopic amplitudes: (a) if the amplitudes

Card 2/4

S/055/62/042/003/046/049
E108/R102

Measurement of the total cross ...

$A_1^{1/2}$ and $A_1^{3/2}$ are zero, then the $A_2^{3/2}$ will be considerably smaller than $A_0^{1/2}$: $5.1|A_2^{3/2}|^2 \leq |A_0^{1/2}|^2 \leq 5.7|A_2^{3/2}|^2$; (v) if it is considered that σ_1 and σ_2 are determined mainly by $A_1^{1/2}$ and $A_1^{3/2}$, then the phase shift of these amplitudes is about 180° , and their moduli are connected by the relation $|A_1^{3/2}| \approx 2|A_1^{1/2}|$. For incident pion energies of 340 Mev the maximum total energy (c.m.s.) of two pions is 400 Mev. If the case (a) applies, one may state that the pions in the energy range 200-300 Mev will interact mainly in states with total isotopic spin $T = 0$ and not with $T = 2$. Professor B. M. Pontekorvo and P. F. Yeremelev are thanked for advice and discussions. There are 5 references: 2 Soviet and 3 non-Soviet. The references to English-language publications read as follows: J. TITLE: Interaction of π^- mesons with hydrogen at 340 Mev

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 44,
no. 1, 1963, 116-126

TEXT: The reactions $\pi^- + p \rightarrow \pi^- + \pi^+ + n$, $\pi^- + p \rightarrow \pi^- + \pi^0 + p$, and
 $\pi^- + p \rightarrow \pi^- + \gamma + p$ were studied with a 25 cm liquid hydrogen bubble
chamber in a 12,000-oe magnetic field. The π^- meson beam was generated
in the synchrocyclotron of the Laboratoriya yadernykh problem OIYaI
(Laboratory of Nuclear Problems OIYaI), the meson energy was 340 ± 15 Mev.
1400 two-pronged stars were found in 16,000 stereoscopic photographs.
Those listed in Table 2 complied with the following conditions: (1) the
angle α between the track of the incident particle and the central plane
of the chamber must not exceed $\pm 4^\circ$; (2) the π^- meson track must not be
shorter than 10 mm; (3) the distance between the point of interaction
and the boundary of the visible range of the working volume of the chamber.

Card 1/3

Interaction of π^- mesons with ...

S/056/63/044/001/022/067
B104/B144

must not be smaller than 20 mm; (4) the azimuthal angle of a negative particle must not exceed 70° ; (5) the noncomplanarity of elastic interactions must not exceed 3° . The angular distributions and the energy distributions of the secondary particles suggest an effect due to resonance of the spin with the isospin $3/2$. A steep increase of the $\pi\pi$ interaction cross section with a total isospin $T = 0$ was found by analyzing the energy distribution in the $(\pi^+\pi^-)$ c.m.s. There are 10 figures and 2 tables.

TITLE: Improvement of the Thermal Condition of the Reverberatory Furnace at the Kirovgrad Copper-Smelting Kombinat (Uluchsheniye teplovogo rezhima otrazhatel'noy pechi Kirovgradskogo medeplavil'nogo kombinata).

PERIODICAL: Tsvetnye Metally, 1958, ³¹ Nr.8, pp.70-72 (USSR)

ABSTRACT: A group of workers at the Kirovgrad Copper-smelting Kombinat proposed an improved burner construction for the reverberatory furnace. The old burners (Fig.1) ("Copper Queen", medium pressure) had a central fuel oil pipe and an annular air pipe (air at 150-200 mm Hg gauge). The new burner (Fig.2) has a further annulus fed with converter air (at 0.8-1 atm. gauge) to improve atomization and combustion. The addition of high-pressure air should have reduced drop size, according to Prof. Selivanov's calculations. Preliminary tests showed that the flame length (8.5 m) was within the optimal value recommended by I.D. Semkin and M.D. Shabli. Operating results have shown a fuel saving of 0.00396 tons/ton of charge.

TITLE: Optimum Working Conditions for Basic Bricks of Open-Hearth Furnaces**PERIODICAL:** Stal', 1960, No. 12, pp. 1086-1092

TEXT: In order to investigate the factors influencing the useful life of magnesite-chromite bricks used for open-hearth furnace roofs tests were carried out in the Nizhnecherek Metallurgical Combine (1957-1959) with furnaces fired a) with coal only ("caout type furnace"); b) with blast-furnace coke and an addition of 20 kg/hour of tar ("seas-type" furnace); c) with blast-furnace coke and an addition of 500-700 kg/hour of coal tar. ("mixed-type" furnace). The tests served to determine the temperature of the magnesite-chromite bricks at various distances from the working surface of the roof, the composition of the atmosphere under the roof, the quantity and composition of dust and the rate of the decomposition in bricks. For these purposes the following devices were employed: (a) KF (KF) type photoelectric pyrometer, platinum-rhodium and platinum thermocouples, mounted in a 75 x 75 x Card 1. []

450 mm magnesite-chromite rod; the hot junction of the thermocouples being at 0, 10, 15 and 30 cm distance from the working surface. Where the hot junction was placed immediately on the surface, it was protected by a silicon-rich cap with a wall 0.8 mm thick; a silicon-potentiometer with a disc scale rotating at 0.5 rph for gas analysis (TNI) type and for random tests BTM-2 (TNI-2) type analyzers were used. The melting dust under the roof was collected by a water cooled detachable brass tube connected in series with water filter, cascade and injectors. For introducing the apparatus in the underroof area 7 channels (90 x 80 mm) were made in the roof. In the tests the relationship between the character of temperature change of the working roof surface and the duration of break in firing, the opening of the charging doors, the time during which cold materials are in the furnace, the duration of various processes and repairs were investigated for all three types of furnaces. It was found that the useful life of the roof in the first place depended on the kind of fuel used, on the place where fuel was fed in the furnace and on thermal loads. The shortest useful life was observed for coal-fired furnaces, working under unfavorable atmospheric conditions. Less frequently, carbohydrates were occasionally found in the roof suds. Even when

Card 2. []

part of the 2nd fuel was replaced by a liquid (max. 500-700 kg/hour) the useful life of the roof was shortened mainly when charging masti or tar through tuyeres mounted at the external side of the fuel tanks. Hydrocarbons are harmful because the glassy surface of the bricks acts as a catalyst and promotes their decomposition during heating and thereby also the activation of oxidation-reduction processes which deteriorate the iron-rich zones of the refractory bricks. Then, firing with partly liquid fuel, the all-liquid fuel the temperature conditions are also adversely affected because the velocity of temperature changes on the working surface increases during heating (up to 500°C/min), the temperature drop can attain 200-300°/min in this interval the cooling time of the roof increases during heating while the temperature can decrease to 1,100°C and lower. When roiling below 1,100-1,450°C, the refractory bricks deteriorate considerably under the effect of temperature change, because the working zones of refractory material pass from a semi-plastic heat-resistant condition into a brittle, non-hail-resistant state.

All, however, in some cases (when repairing the roof), the cooling (for instance, during repair) does not increase deterioration of the bricks, it can be assumed that, actually not cooling (that), but its accompanying phenomena, such as speed

Card 3. []

9/13/60/000/012/003/015
404/2027

Optimum Working Conditions for Basic Bricks of Open-Hearth Furnaces
and frequency of heat charges during the non-heat-resistant period of the working zones in refractory bricks are the causes of their decomposition. The best of operation conditions of the roof is, when it is not cooled below 1,500°C. However, with the present methods of charging high-capacity furnaces this can be obtained only by extending the charging time or by intensifying the combustion of fuel, then having to cool the roof under 1,450-1,500°C during charging, the number of reverberals should preferably be reduced by intensifying combustion as much as possible, and by increasing the intervals between reverberals. As the chances in the composition of blast gases under the roof, resulting from 7.9 simulated, add to the decomposition of the refractory bricks, care should be taken to prevent any reducing medium from entering this area, not even for a short time. Refractory brick should be made more quickly in the first phase of the furnace campaign than in the subsequent phase. This shows that decompositon takes place quickly when there are refractory bricks with a high content of iron oxides in the working area. There are 6 figures, 6 tables and 3 series of references.

TITLE: An Experiment in Operating an Industrial Apparatus for Zone-melting Tin (Opyt pusk i ekspluatatsii promyshlennoy ustancovki dlya zonnnoy plavki olova)

PERIODICAL: Tsvetnyye Metally, 1959, Nr 3, pp 32 - 37 (USSR)

ABSTRACT: The results of laboratory experiments indicated that zone-melting of wide flat specimens was possible. In the laboratory zone-melting was carried out in quartz vessels 280 x 190 x 15 mm, using overhead Silit resistance heaters (Figure 1). At first, insulating bricks were placed all round the apparatus but this formed a wide molten zone in the centre (Figure 1a). This was overcome by removing insulation from under the centre of the vessel. For the experimental industrial apparatus a vessel 480 x 190 x 15 mm was at first used. The apparatus was redesigned with the help of A.S. Ivannikov, A.M. Yegorov and L.L. Meshkov of the Novosibirsk Lead Works. It consisted of a graphite vessel 1220 . 400 mm, taking 60 kg Sn. The bottom of the vessel was tilted (Figure 2). The vessel was in a case on a portable stand and asbestos cement plates were

Card1/4

SOV/136-59-3-9/21

An Experiment in Operating an Industrial Apparatus for Zone-melting
Tin

used as supports and insulators. The middle was open to the air. The speed of traverse of the vessel under the heaters was 16, 22, 33 or 44 mm/h and the return speed was 190 mm/min. The heaters were 900 mm long with a resistance of 3.5 Ω each. The distance between the heaters and the metal could be varied from 1 to 3 mm. The current was controlled by an autotransformer. Electrolytically refined tin was used. The zone width was not greater than 65 mm with the solid-metal interface vertical. There were six heaters, 190 mm between each. One cycle is shown in Figure 4. After moving 190 mm, the vessel returns to its original position so that the first zone is under the second heater, the second zone under the third heater and so on. It stays in this position for 15 minutes to allow the zone under the first heater to become molten before the next cycle begins. After the second cycle the zones have moved another 190 mm and after six cycles the first zone reaches the end. The maximum purification is obtained after 40 cycles.

Card2/4 The table gives the spectrographic analysis of the zone-

SOV/136-59-3-9/21

An Experiment in Operating an Industrial Apparatus for Zone-melting Tin

refined tin. No elements were detected. The yield of pure metal is 60% of the length but because of the sloping bottom it is 85% by volume. The production obtained is 145 kg/month using 40-45 kWh/kg tin. During zone-melting the tin is covered from the very beginning by a thin but strong oxide layer. This plays an important part as it absorbs heat easily and protects the tin from contamination and further oxidation. This enables industrial zone-melting of tin without a protective atmosphere. The purity of the tin obtained was measured by an electrical method by the Institut fizicheskikh problem AN SSSR (Institute of Physical Problems of the Ac.Sc., USSR) and found to be 99.9998% Sn. The described method is recommended for metals with melting points less than 600 - 650 °C which form a protective oxide film. Results indicate the possibility of refining bismuth, indium and zinc by similar methods.

SELIVANOV K.P.

1495. THE RESULTS OF THE 1951-1956 CAMPAIGN AGAINST PARASITIC DISEASES IN UKRAINIAN SSR. THE AIMS OF THE 1956-1960 CAMPAIGN AND A PLAN OF UNDERTAKINGS FOR 1956 (Russian text) - Selivanov K. P., MED. PARAZIT. 1956, 25/3 (207-209)

During the period 1951-1955 the incidence of malaria fell by 96.2%; in Kiev and south-eastern provinces of the Ukraine a reduction of the incidence of helminthiasis was observed and some success was achieved in the fight against enterobiasis (in 224 nurseries and similar children's institutions in 9 provinces this form of infestation was totally eliminated). In the north-western provinces, however, the results were poor (the special network of clinics having been almost totally destroyed) and no reduction of the incidence of ascariasis and trichocephaliasis has been achieved. The sixth five-year plan anticipates total elimination of malaria, taeniasis, marked reduction in the incidence of ascariasis and trichocephaliasis and elimination of enterobiasis from nurseries and other pre-school children's institutions. Intensification of the campaign against the larvae of *Musca domestica* and the blood sucking insects is foreseen. In order to fulfil the plan a wider educational campaign for medical workers in parasitology is necessary and anti-malarial and medical parasitology departments of epidemiologico-sanitary stations must be put on proper footing. GAS PRESSURE WELDING OF RAILWAY WAGON PARTS. T. A. VLADIMIRSKIY, K. V. Selivanov,
A. K. Shvylpov, and N. V. Pashkov. (Avtol Delo, 1949 No. 12, pp. 16-19) (In Russian)

It has been found advantageous in the repair of railway wagon parts to replace the
forge and flash-welding processes previously used by gas pressure-welding, and
examples are given of the successful use of this method. SK

Title : Gas-pressure welding of locomotive piston and drive rods

Periodical : Vest. mash. 34/8, 68-71. Aug 1954

Abstract : An account is given of researches made of welded joints on defective piston and drive rods taken from locomotives in actual operation. The SGP-7u gas-pressure machine was developed for rods having a cross section of 6,500 to 8,000 mm². A description of this machine is given and data are presented on the quality of its work. Illustrations; graphs; table.

TITLE: Properties of Gas-Press Welded Joints of Cast and Rolled
Large-Section Metal (Svoystva soyedineniy litogo i prokat-
nogo metalla bol'shikh secheniy, vypolnennykh gazopressovoy
svarkoy)

PERIODICAL: Svarochnoye proizvodstvo, 1958, Nr 2, pp 25 - 28 (USSR)

ABSTRACT: The article presents results of experiments on gas-press
welding of large-section (20,000 to 25,000 mm²) steel
parts, where rolled with cast, rolled with rolled , and
cast with cast parts were joined. Until now, this method
was used in the USSR and abroad only for joining round sec-
tions not over 8,000 to 10,000 mm², whereas the described
method obtains fully satisfactory joints in low-carbon steel
sections of 22,500 mm². The described experiments, super-
vised by T.A. Vladimirovskiy, were performed on gas-press
equipment developed by the TsNII for welding parts up to
50,000 mm² and with the use of a multiple flame torch
("MG-PR") with an acetylene consumption of 21,000 m³/hr.

TITLE: New Machines and Torches for Gas-Press Welding (Novyye
stanki i gorelki dlya gazopressovoy svarki)

PERIODICAL: Svarochnoye proizvodstvo, 1958, Nr 8, pp 30 - 35 (USSR)

ABSTRACT: Information is given on special equipment, used for welding railroad rolling-stock parts in the Soviet Union, developed at TsNII MPS under the supervision of T. A. Vladimirskiy, Candidate of Technical Sciences. The welding stand (fig.1-3) equipped with a torch oscillating device for welding parts with a cross-section area up to 50,000 sq mm. The "SGP-8u" welding machine (fig.4) for the repair of large-size locomotive parts. Multiple flame torches such as: "MG-PR" (fig.5) for welding and heat treatment of large-section parts; "MG-120" (fig.6) for welding cylindrical parts up to 120 mm in diameter; "MG-80" to weld rods up to 90 mm in diameter; "MGD" (fig.7) and "MG-DS" (fig.8) for repair
